

Summary of my Findings

Digital Hound Dogs Investigations conducted a forensic analysis of the evidence provided in the case involving David Eng and MyFace. The objective was to determine whether the unauthorized posting of sensitive photographs resulted from a compromise of the MyFace server or of David Eng's personal computer.

The investigation included a review of server network activity, forensic tool outputs, malware indicators, and workstation artifacts. The MyFace server evidence consisted primarily of netstat reports, network forensic screenshots, and server analysis outputs. While these reports showed active network connections and normal service activity, there was no definitive evidence of unauthorized access, malicious persistence, privilege escalation, or successful compromise of the MyFace server or network.

In contrast, analysis of David Eng's personal computer indicated a compromise. Multiple logical drives were identified and reviewed. Screenshots from the workstation contained evidence of suspicious activity, including the presence of clearlogs.exe, a utility designed to remove event logs and obscure evidence of user actions. Such tools are commonly associated with attempts to conceal malicious activity. Forensic reports suggested malware-related activity and abnormal system behavior consistent with a compromised endpoint.

Based on the available evidence, we have determined that David Eng's personal computer was the most likely point of compromise. The evidence does not support the claim that the MyFace server was hacked and used to obtain or distribute the photographs in question. Instead, the findings indicate that malware or unauthorized access to David Eng's device likely exposed his information and led to the posting of the photographs.

The forensic evidence supports the conclusion that MyFace was not responsible for the compromise. The incident originated from David Eng's personal computer, which contained the strongest indicators of unauthorized activity. These findings may be used by MyFace in court to demonstrate that its server infrastructure was not the source of the breach.
